Slopcloud

I will be planning on making a website that stores and plays music. My ideal for this website would be to have it to where any user could add music to it, but for it to have to be approved by an admin for it to show up on the page for everyone to listen to. I would also like it to have the basic music app features like shuffle, playlists etc. It would also have search functions where you could search by name, artists, genre. It wouldn't have too many pages, as for the best possible implementation I would say most of these features would be more so popups rather than dedicated pages.

List of pages:
1. Main landing page
2. Account page (has all the account stuff like uploaded songs and playlists)
3. Search page (shows relevant songs based on search)
4. FAQ

The information that would need to be stored and manipulated would be the audio files themselves, as well as all the information relating to them, like the song name, author, and genre. Like mentioned above only an admin would be able to add all of this to be displayed on the site, but any user could add a song with all of the relevant information that would then be shown only to the admin to finally be pushed to the site.
